First Parent

Second Parent

Step 1: Select a random fragment of the first parent and inherit it in place

Step 2: Start from the second cutting point and complete circularly with the visits of the second parent

2 Dynamic Variant ► customer penalty

earliest arrival of
time window

latest arrival of
time window

time window width
| latest arrival-
earliest arrival |

demand

service duration

duration from depot

2 Dynamic Variant ► customer penalty

- **Calculate penalty**

The penalty of node i can be calculated with its own information.

$$penalty[i] = a * latestArrival[i] + b * duration[depot, i] + c$$

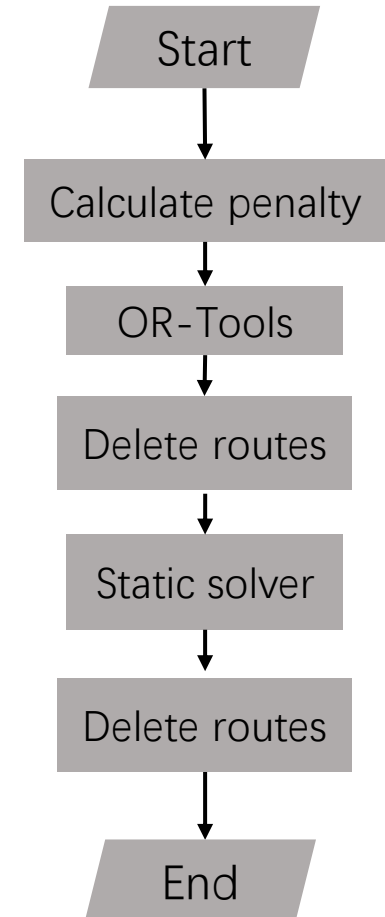

where a, b, c are constants.

- **OR-Tools**

Input the known information and penalties into OR-Tools, and solve the problem with the method “Penalties and Dropping Visits” .

- **Delete routes**

After we get the solution from the solver, calculate the latest departure time of each route. If it is less than constant t , delete that route.
